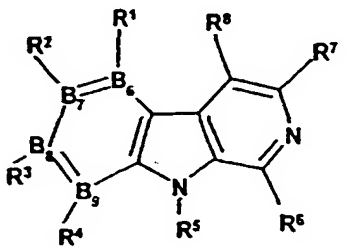
(54) Title: SUBSTITUTED BETA-CARBOLINES WITH IKB-KINASE INHIBITING ACTIVITY



(I)

(57) Abstract: Compounds of the formula (I) are suitable for the production ofpharmaceuticals for the prophylaxis and therapy of disorders in whose course an increased activity of IκB kinase is involved.

Description

SUBSTITUTED BETA-CARBOLINES WITH IKB-KINASE INHIBITING ACTIVITY

The invention relates to novel substituted beta-carbolines, a process for their preparation and use thereof as pharmaceuticals.

United States Patent 4,631,149 discloses beta-carbolines useful as antiviral, antibacterial and antitumor agents. United States Patent 5,604,236 discloses beta-carboline derivatives containing an acidic group, useful as thromboxane syntheses inhibitors.

NFkB is a heterodimeric transcription factor which can activate a large number of genes which code, inter alia, for proinflammatory cytokines such as IL-1, IL-2, TNFα or IL-6. NFkB is present in the cytosol of cells, building a complex with its naturally occurring inhibitor IkB. The stimulation of cells, for example by cytokines, leads to the phosphorylation and subsequent proteolytic degradation of IkB. This proteolytic degradation leads to the activation of NFkB, which subsequently migrates into the nucleus of the cell and there activates a large number of proinflammatory genes.

In disorders such as rheumatoid arthritis (in the case of inflammation), osteoarthritis, asthma, cardiac infarct, Alzheimer's disease or atherosclerosis, NFkB is activated beyond the normal extent. Inhibition of NFkB is also of benefit in cancer therapy, since it is employed there for the reinforcement of the cytostatic therapy. It was possible to show that pharmaceuticals such as glucocorticoids, salicylates or gold salts, which are employed in rheumatic therapy, intervene in an inhibitory manner at various points in the NFkB-activating signal chain or interfere directly with the transcription of the genes. The first step in the signal cascade mentioned is the degradation of IkB. This phosphorylation is regulated by the specific IkB kinase. To date, no inhibitors are known which specifically inhibit IkB kinase.

In the attempt to obtain active compounds for the treatment of rheumatoid arthritis (in the case of inflammation), osteoarthritis, asthma, cardiac infarct, Alzheimer's disease, carcinomatous disorders (potentiation of cytotoxic

therapies) or atherosclerosis, it has now been found that the benzimidazoles according to the invention are strong and very specific inhibitors of IkB kinase.

The invention therefore relates to the compounds of the formula I

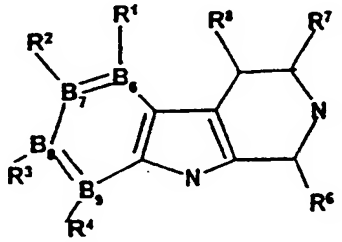
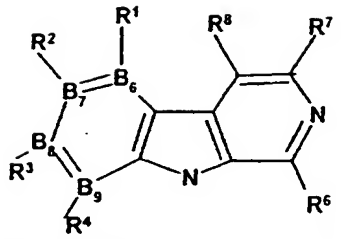
and is reacted with hydrazine hydrate and later with formaldehyde (R^6 is H) or R^6CHO to give a compound of formula VI



(VI)

and oxidized to give a compound of the formula VII,



(VII)

where R^1 to R^4 and B_6 to B_9 are as defined in formula I and R^5 is hydrogen atom, or

Pharmacological examples

I_KB-kinase ELISA

The in-vitro assay for detecting and measuring inhibition activity against IκBα-kinase complex by candidate pharmacological agents employs a biotinylated polypeptide spanning both Ser^{32} and Ser^{36} of IκBα and a specific antibody binding only to the phosphorylated form of the polypeptide, being either monoclonal or polyclonal (such as the commercially-available anti-phospho-$serine^{32}$ IκBα antibodies from New England Biolabs, Beverly, MA, USA, cat. #9240). Once the antibody-phospho-polypeptide complex is formed, the complex can be detected by a variety of analytical methods utilizing such as radioactivity, luminescence, fluorescence or optical absorbance. For the use of the ELISA method, the complex can be immobilized either onto a biotin-binding plate (such as Neutravidin coated plate) and detected with a secondary antibody conjugated to HRP, or onto an antibody-binding plate (such as Protein-A coated plate) and detected with biotin-binding protein conjugated to HRP (such as Streptavidin-HRP). The level of activity can be correlated with a standard curve using synthetic phosphopeptides corresponding to the substrate polypeptide.

Experimental

IκBα kinase complex was prepared by first diluting 10 mL of HeLa S3 cell-extracts S100 fraction with 40 mL of 50 mM HEPES pH 7.5. Then, 40% ammonium sulfate was added and incubated on ice for 30 minutes. Precipitated pellet was redissolved with 5 mL of SEC buffer (50 mM HEPES pH 7.5, 1 mM DTT, 0.5 mM EDTA, 10 mM 2-glycerophosphate), clarified by centrifugation at 20,000 x g for 15 min., and filtration through a 0.22 µm filter unit. Sample was loaded onto a 320-mL Superose-6 FPLC column (Amersham Pharmacia Biotech AB, Uppsala, Sweden) equilibrated with SEC buffer operated at 2 mL/min flow rate at 4°C. Fractions spanning the 670-kDa molecular-weight marker were pooled for activation. Kinase-containing pool was then activated by incubating with 100 nM MEKK1Δ, 250 µM MgATP, 10 mM $MgCl_2$, 5 mM DTT, 10 mM 2-glycerophosphate, 2.5 µM Microcystin-LR, for 45 minutes at 37°C. Activated enzyme was stored at –80°C until further use. Per well of a 96-well plate, compounds at various concentrations in 2 µL DMSO were pre-incubated for 30 minutes at 25°C with 43 µL of activated enzyme diluted [1:25] with assay buffer (50 mM HEPES pH 7.5, 5 mM DTT, 10 mM $MgCl_2$, 10 mM 2-glycerophosphate, 2.5 µM Microcystin-LR). Five

microliters of peptide substrate (biotin-$(CH_2)_6$- DRHDSGLDSMKD-$CONH_2$) at 200 µM stock solution was added to each well and incubated for 1 hour before quenching with 150 µL of 50 mM HEPES pH 7.5, 0.1% BSA, 50 mM EDTA, plus [1:200] antibody. Quenched kinase reaction samples and phospho-peptide-calibration standards (biotin-$(CH_2)_6$- DRHDS[PO_3]GLDSMKD-$CONH_2$, serially diluted in assay buffer) at 100 µL per well were transferred to a Protein-A plate (Pierce Chemical Co., Rockford, IL, USA) and incubated for 2 hours. with shaking. Following 3 washes with PBS, 100 µL of 0.5 µg/mL Streptavidin conjugated with HRP (horseradish peroxidase) diluted with 50 mM HEPES/ 0.1% BSA, was added for 30 minutes. After 5 washes with PBS, 100 µL TMB substrate (Kirkegaard & Perry Laboratories, Gaithersburg, MD, USA) was added and color development was stopped by adding 100 µL of 0.18 M H_2SO_4. Absorbance signals were recorded at 450 nm. Calibration-curve standards were fitted by linear regression using a 4-parameter dose-response equation. Based on this standard curve, levels of kinase activity were calculated in order to determine inhibition activity of candidate pharmacological agents.

Table 3 which follows shows the results.

Mouse heterotopic cardiac transplant model

In the mouse heterotopic cardiac transplant model across full histocompatibility barriers (BALB/c->C57BL/6 or B6/129), graft survival is typically limited to 7.3 ± 0.4 days (mean ± SD, n0 allografts) (see for example in Hancock WW, Sayegh MH, Zheng XG, Peach R, Linsley PS, Turka LA. Costimulatory function and expression of CD40-ligand, CD80 and CD86 or in vascularized murine cardiac allograft rejection. Proc Natl Acad Sci (USA) 93, 1996, 13967-13972; and Hancock W W, Buelow R, Sayegh MH, Turka LA. Antibody-induced transplant arteriosclerosis is prevented by graft expression of anti-oxidant and anti-apoptotic genes. Nature Med 4, 1998, 1392-1396).

The effects of oral administration of the compounds according to examples 49 and 60 were tested using 25 mg/kg/day for 14 days, starting at transplantation in said animal model. Whereas grafts in animals receiving the carrier, methyl-cellulose, rejected by 7 days (6.7 ± 0.8), grafts in compound 49-treated mice survived around 15 days (15.3 ± 0.6), and grafts in those given compound 60 survived for 20 days (20 ± 1). Current immunosuppressive therapies used in transplantation have limited efficacy and/or considerable toxicity. Targeting of IkB-kinase with these agents significantly prolonged allograft survival without associated toxicity.
